Temperature levels & escalation

Base ΔT ladder: <0.5°C = NONE · 0.5–<1.0°C = LOW (fan AUTO) · 1.0–<3.0°C = MEDIUM · ≥3.0°C = HIGH.

Fast momentum (15 min): ≤-0.10°C/h = cooling fast · -0.10–-0.03 = cooling · -0.03–<+0.04 = stable · +0.04–<+0.10 = warming · ≥+0.10 = warming fast. After startup, rates must stay plausible for 5 min: sustained warming then arms thermal pressure over 10 min. The Momentum card shows exactly what is learning, blocked, arming or active. Once armed, warming or stable pressure escalates the base demand one step (LOW → MEDIUM, MEDIUM → HIGH), while fast warming requests HIGH. Genuine cooling below -0.03°C/h suppresses the boost; the pressure latch releases after 15 min without qualifying warming.

Heat memory: recent gain is current indoor temperature minus the lowest indoor temperature seen over roughly 2 hours. <0.5°C adds nothing. At ≥0.5°C, Crispy escalates the base demand one useful step (LOW → MEDIUM, MEDIUM → HIGH). At ≥1.0°C, it requests HIGH. Heat-memory escalation only applies above target + 0.3°C, with at least 0.5°C cooling advantage and a safe intake temperature.

Auto target band: restart at target +0.3°C, release at target; within 0.5°C, thermal boosts are capped at MEDIUM. ATTACK applies the capped thermal demand. After 15 min of settled boost observations, CRUISE tests native AUTO regardless of wattage. The first 15 min after release are settling time. A further 5 min above +0.10°C/h and at least +0.15°C/h worse than the baseline returns to ATTACK. Stable temperature under solar load is success. Changed intake, bypass or independent demand invalidates the comparison. Retry waits 45 min, or a sustained 2°C intake improvement. FULL SEND stays HIGH while useful cooling is needed. Moisture and laundry demand remain independent.

INTAKE SUPPLY INDOOR Cool-air delivery Duct / unit heat pl...

Air path: Intake is outside air entering the HRC; Supply is what reaches the apartment. Cool-air delivery shows how much of the available temperature advantage reaches the supply. Heat recovery is warming between intake and supply.

Relative humidity is temperature-dependent, so Crispy also calculates absolute humidity. **Drying advantage = indoor AH - intake AH;** positive means ventilation can export moisture. Moisture control uses hysteresis; 1 and dry Mode uses the same.

Moisture & Laundry Laboratory

Absolute humidity · 12h
12 g/m³

Drying opportunity · 12h
3.0 g/m³

Moisture demand · 12h
3.0

Laundry lab: absolute humidity is actual water content in the air. Positive Drying Opportunity means indoor air contains more water per cubic metre than intake air, so ventilation can export

Flight Recorder: demand levels use 0=NONE, 1=LOW, 2=MEDIUM, 3=HIGH. Thermal Base shows the normal ΔT ladder, Momentum Boost shows sustained heat-rise rejection, Heat-memory Boost shows senilation after accumulated temperature.

About Crispy

Crispy is a supervisory controller over the existing HRC. It combines live free-cooling, a rolling 24-hour heat forecast, thermal momentum, heat-gain memory, moisture demand and Laundry Drying Mode. **ATTACK** applies the required fan demand, **CRUISE** tests native AUTO, **RELEASE** returns the virtual remote to fan AUTO. **FULL SEND** remains HIGH until target. Live supply temperature can veto the forecast, Guest Quiet suppresses Crispy boosts, and native ventilation stays in charge whenever a...
